

REPO SUMMARY

coupon-site

CouponHub/CouponPush is a coupon and deals web app with shopper-facing pages plus an admin CMS for managing stores, coupons, deals, messages, and settings. The repo contains a React storefront, PHP-rendered pages, PHP JSON APIs, and a MySQL schema.

WHO IT'S FOR

Primary persona: price-conscious online shoppers in India looking for verified promo codes, store-specific offers, and seasonal savings across categories like electronics, fashion, food, travel, beauty, and grocery. **Admin operators are also supported** through repo-backed management pages.

WHAT IT DOES

- Shows featured and latest coupons, featured stores, and featured deals on the homepage.
- Organizes offers by store, category, coupon page, and search results.
- Supports seasonal or festival offer pages through dedicated seasonal offer tables and API routes.
- Tracks coupon and deal clicks through ``api/track-click.php`` and click counters in MySQL.
- Captures newsletter subscribers and contact form messages in database tables.
- Adds SEO metadata and schema markup on home, store, and search pages.
- Provides admin pages for coupons, stores, categories, deals, settings, subscribers, and messages.

HOW IT WORKS

- **Frontend:** ``frontend/src/App.tsx`` wires React Router pages such as home, store, category, coupon, search, contact, privacy, and seasonal offers.
- **Data access:** ``frontend/src/services/api.ts`` fetches ``/api/*.php`` endpoints for stores, coupons, deals, categories, seasonal offers, search, stats, and click tracking.
- **Backend/API:** ``api/config.php`` sets JSON/CORS helpers; endpoint files query MySQL and return `{ success, data }` responses.
- **Shared services:** ``config/database.php`` provides a PDO singleton, while ``includes/functions.php`` centralizes helpers, search, click tracking, featured content queries, auth checks, and settings reads.
- **Storage/admin:** ``database/schema.sql`` defines users, categories, stores, coupons, deals, subscribers, contact_messages, click_tracking, and settings; ``database/seasonal_offers.sql`` extends this for seasonal campaigns; ``admin/*.php`` manages the same data.

HOW TO RUN

1. Import ``database/schema.sql`` into MySQL. Import ``database/seasonal_offers.sql`` if you want seasonal offer support.
2. Set DB credentials in ``config/database.php``.
3. Serve the repo from a local PHP/Apache path matching ``http://localhost/coupon-site`` and start MySQL; the repo references XAMPP Apache in ``HomePage.tsx``, and ``frontend/vite.config.ts`` proxies ``/api`` and ``/uploads`` to that URL.
4. In ``frontend/``, run ``npm install`` then ``npm run dev`` to launch the React app on port ``5173``.

One-command local bootstrap, Docker, or Compose setup:

Not found in repo.

Repo note: branding is mixed in source and docs (``CouponHub`` in schema/deployment/settings, ``CouponPush`` in React SEO and UI copy).
